

1. It is a formula expression language used in Microsoft products like Power BI and Power Pivot in Excel for data analysis and calculations.

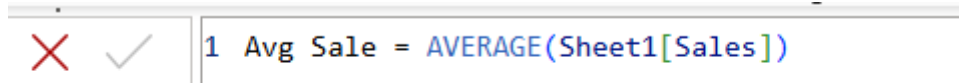

- 2.
3. Calculated column works with all rows and measure shows only aggregations

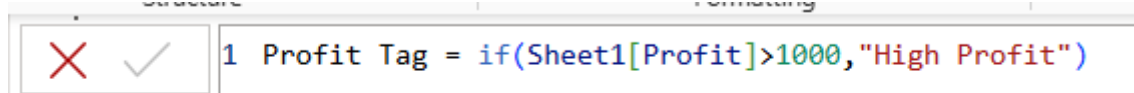

- 4.
5. COUNTROWS() function is used to count the number of rows in a specified table

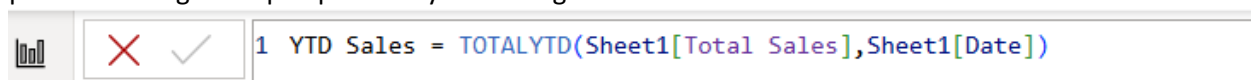

- 6.

- 7.

- 8.
9. This means the calculation of one column depends on another, and that second column also depends on the first, forming a cycle.
10. Essentially, row context provides the "local" perspective of a single row, while filter context provides the "global" perspective by restricting the data considered.
